

* Bell ringer

1. Predict the charges
2. Write the formula

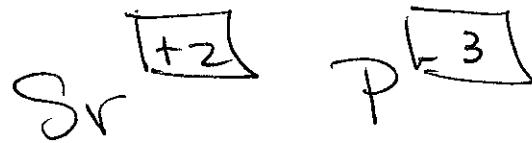

Strontium Phosphorus

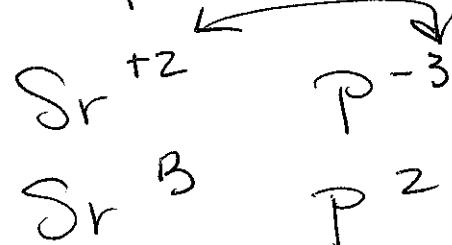

Shortcut time!

* Take it, flip it, drop it down
for ionic!

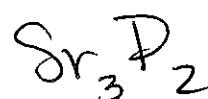

1. Take the charges

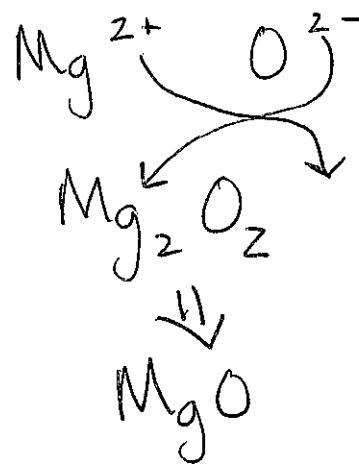

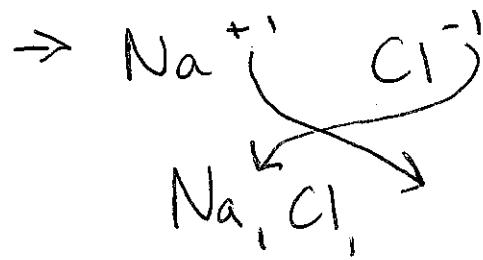

2. Flip it

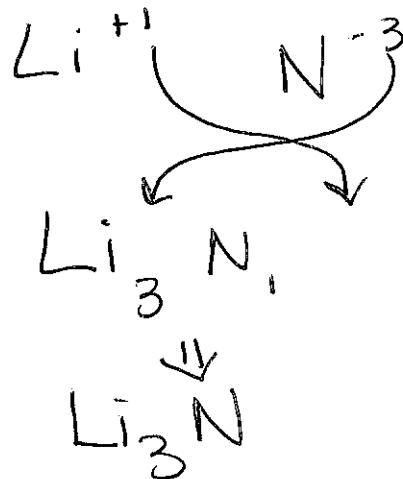

3. Drop it down

Practice:

* Always remember to
simplify the
subscripts.

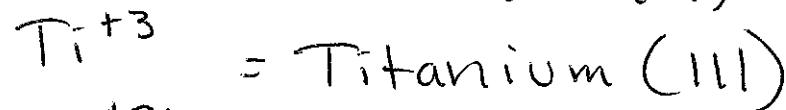

* Ionic Compounds with multiple charges

* Transition Metals

↳ have multiple charges.

+ This is why we have skipped them so far

~~Titanium~~

* Always cations! (+ charge)

When writing, use roman numerals

$$1 = \text{I}$$

$$2 = \text{II}$$

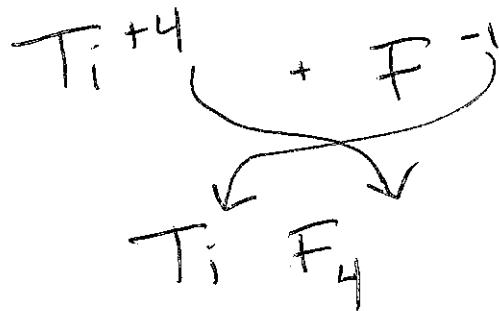

$$3 = \text{III}$$

$$4 = \text{IV}$$

$$5 = \text{V}$$

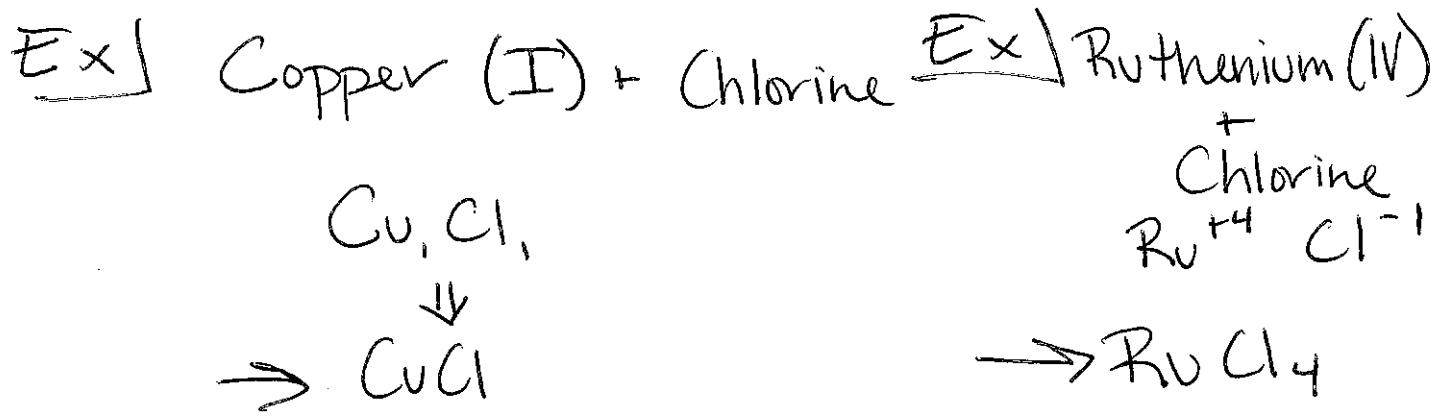

+ 4 by league schools
IV
VI

Ex] Titanium(IV) + Fluorine

Ex] Titanium(III) + Fluorine

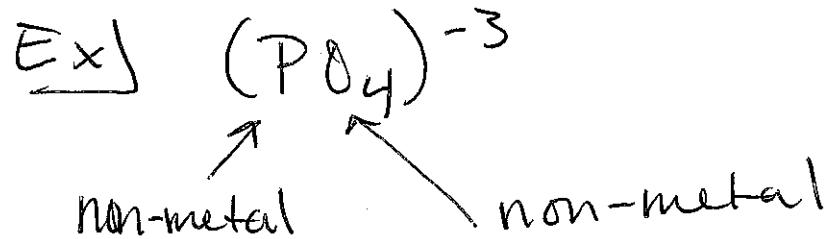

Polyatomic Ions

- Made up of more than 1 atom
(poly = many)

Ex] $(\text{CH}_3\text{COO})^-$ = acetate ion (anion)

$(\text{PO}_4)^{-3}$ = phosphate ion (anion)

- The ion itself is made of covalent bonds

- Entire ~~ion~~ ^{compound} functions as an ion together
- Shown w/ parentheses

$(\text{NH}_4)^-$ Ammonium

$(\text{CN})^-$ Cyanide

- can be cations or anions

Naming Ionic Compounds

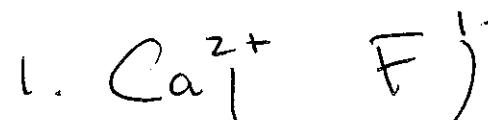

1. Cation always comes first
 - Just write the name of the element
 - Transition metals need to have the charge written as Roman numerals after them.

2. Name the anion BUT change the ending to -ide.

~~E*~~ Oxygen → Oxide
Sulfur → Sulfide

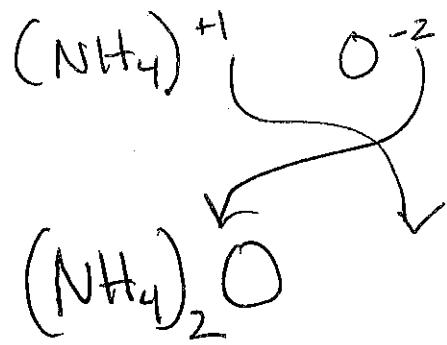

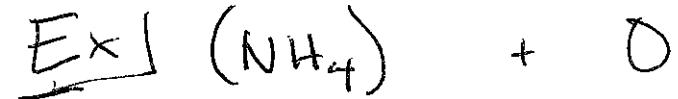

→ Polyatomic ions are named without changing the ending.

Ex] Ca + F

3. Calcium Fluoride

Ex] V^{+4} + N
 V^{+4} + N^{-3} $\rightarrow \text{V}_3\text{N}_4 \rightarrow$ Vanadium(IV) Nitride

Ammonium Oxide

* Special note: Just like in naming, the cation comes first in the formula, too!
